- XIII. Teaching Aids**
- XIV. Potential National Funding Sources**
- XV. TIC Resource Contacts**
- XVI. Letter of Understanding**
- XVII. Sample Grant**
- XVIII. Sample Water Chemistry Log**
- XIX. Release Day Activities** (as submitted by teachers)
- XX. Thoughts on Classroom Activities**

Information in this “How To Raise Virginia Trout” manual was obtained from the Trout In The Classroom website, Commonwealth of Virginia TIC coordinators, various aquarium books, and the personal knowledge and experience of many individuals. It is not represented to be the final authority on raising trout in Virginia, but is presented as a help guide. This manual is always available to be updated/modified as new information or techniques are received. Your input is always appreciated.

10 Tips for a Successful TIC Project

1. Test and record your water chemistry daily.
2. Check that your water temperature is in the low 50's and make sure your chiller is functioning properly.
3. Add Crystal Clear One Fix weekly.
4. Keep your eggs and alevins in the dark by covering your tank with foam board or cardboard (eggs and alevins are light sensitive).
5. Remove all dead eggs, alevins, and fish daily.
6. Siphon gravel and perform water changes once you start feeding your fish.
7. Keep your filter and pump intakes covered with the foam block
8. Do not over feed your fish.
9. Ammonia and Nitrite levels can be reduced by water changes, increasing your dosage of Crystal Clear One Fix to 3 times a week, and adding stream rocks and wood.
10. Set your tank up 30-60 days before your eggs arrive.

Section I. Equipment Needed

Suggested Equipment List:

Item	1 st Year Set-Up	On Going Set-Up
<u>Items from ThatPetPlace.com</u>	KIT #1	KIT #2
Whisper 60 Power Filter	X	
Mag Drive 700 Water Pump w/ 10' cord *	X	
Whisper 20 Air Pump	X	
Battery Operated Digital Thermometer	X	
Crystal Clear One Fix (Provided by your Coordinator)	X	X
Freshwater Master Testing Kit	X	X
20' ½" I.D. tubing *	X	

Dechlorinating Solution	X	X
¼" Check valve	X	
6" Aquarium Net	X	
Foam Block for Aqua Clear for use as prefilters	X	X
12" Air Stone	X	
10' ¼" airline tubing	X	
1 Tube of Aquarium Sealant	X	X
3 Bags of Aquarium Gravel		
Large Gravel Vacuum **	X	X
Battery Operated Weekend Feeder **	X	X
3 Piece Brush Set **	X	X
<u>Other Source Items</u>		
55 Gallon Tank	X	
Chiller	X	
Turkey Baster	X	
Metal or plastic egg basket	X	
Containers for water changes and fry release ***	X	
<u>Home Improvement Store</u>		
Foam Board Insulation	X	
5 Outlet Surge Protector	X	
SS clamps	X	
Lava Stone and Plexiglas	X	

The first year set up costs will be about \$1,200 with ongoing annual expenses about \$50.

*** - Not needed if you use the Tradewinds drop-in chiller**

**** - Not needed 2nd year if purchased in 1st year set up**

***** - The buckets you will need for water changes can be from any source as long as they are clean. As strange as it sounds, plastic kitty litter containers are great as they can hold about 4-5 gallons and have a lid.**

All of the recommended TIC equipment (except the tank, chiller, and items from a home improvement center) is now available in a kit, which can be purchased through That Pet Place. When ordering any of the kits, please contact Stephanie Welsh and make sure you tell her that you are from Virginia. Do not order online or you will lose the TIC discount.

Stephanie Welsh
Senior Business Account Representative
That Fish Place/That Pet Place

It is recommended that at a minimum, you order the Replacement test tubes as these are the most likely things to get broken during the year.

Chiller Options

You will need a chiller to keep the tank's water temperature at about 50° to 55° Fahrenheit. Most chillers are only designed to chill aquarium water to around 60°-70° Fahrenheit. Therefore, for our program, we must purchase chillers that are rated for a larger size tank--for example, for a 55-gallon TIC tank; we purchase at least a 1/4 horsepower chillers, which are technically designed for 100-125 gallon tanks. By using a more powerful chiller, we decrease our chances of burning our chiller out after only a year or two. Additionally, all chillers except the TradeWind DI-25 need a submersible

pump to push the water through. The pump from That Fish Place will work with all those chillers. If you get a different chiller, check the GPM requirements for that pump.

Here are the four of most popular chiller options listed in alphabetic order:

1. Arctica Titanium Chiller– a nearly silent, a flow-through from Marine Depot 1/4 Horsepower - 2 year warranty – flow through type (water is cooled when it is pumped through the cooling chamber) –This unit is UL listed- and purported to be the most quiet of all comparable chillers, which is of great importance to teachers. This chiller **MUST** be used with insulation, or it will wear out too quickly. This unit requires a separate pump, such as the Mag Drive Water Pump.
2. Polar Bear Chiller - available through BE Cooling, 4451 Cleveland Avenue, Stevensville, MI 49127, email: sales@aquastealth.com. The price for their model # CC50 is \$425 plus \$30 for shipping. This unit requires a separate pump, such as the Mag Drive Water Pump. This is a larger unit than previously listed – better capacity and less cycle time.
3. Prime Tower Chiller -- an efficient fairly quiet flow-through available from That Fish Place. With insulation, this chiller comes on only a few times an hour. It can be purchased from That Fish Place. This unit requires a separate pump, such as the Mag Drive Water Pump. If you order this chiller, make sure you include it in your list of equipment to ensure you receive any applicable discount.
4. TradeWind DI-25 drop-in chiller – This is a drop-in the tank chiller recently tested by the Winchester chapter and found to be quite good. They experienced no problems and they ran for the whole school year with no adjustments needed, and no noise issues. The price is \$505 including the \$20 upgrade of a "U-tube" so the hoses do not kink when draped over the tank edge. Contact Hal Collier, twchillers@sbcglobal.net; the website is: <http://www.tradewindchillers.com/>. Hal can be reached by phone Monday through Friday, 8:00 am to 4:00 pm at 760-233-8888, or by fax at 760-233-8889. One benefit of this chiller is the elimination of the Mag Drive 700 pump and tubing (cost saving of \$81.80).

Section II. Tank Set Up

Locate a suitable place in the classroom for the tank setup. It should be away from direct sunlight, as sunlight will increase the water temperature putting a greater strain on the chiller and will promote the growth of algae increasing the tank cleaning time. A lab-type counter or bench is preferred. The surface must be stable and capable of supporting a tank, 55 gallons of water, and gravel (approximately 500 lbs).

Activities your students can do before your eggs arrive

Making the Lava Stone Bioboard

Lava stone (the purplish kind you find bagged at Lowe's or Home Depot) makes an outstanding "home" for the bacteria necessary to convert ammonia into harmless compounds. It's large surface area due to the fissures and cracks provide ample area for the bacteria to grow.

1. After obtaining the lava stone, rinse it well to remove the dust and other loose material and let it dry thoroughly (usually a day in the sun). While at Lowe's or Home Depot, also obtain a 12" x 12" piece of 1/4" Plexiglas. Make sure that the piece of Plexiglas will fit in your tank on one of the ends. Otherwise, have it cut to fit.
2. Using Aquarium Sealant (found in your kit), glue enough pieces of Lava Stone to the Plexiglas to cover as much of the Plexiglas as possible.
3. Lay it flat and let it cure for 48 hours.
4. Install in tank by placing it against the end wall opposite your filter outflow tube with a slight lean and position some gravel to hold in place. By putting it at the other end of the tank from the filter outflow tube, the lava stone will receive a constant flow of water thereby remaining productive.
5. Do not remove the Plexiglas sheet until you break the tank down for the year. Any debris that may accumulate on the bioboard during the year may be suctioned off when you are cleaning the tank.

If you choose, you don't have to make the bioboard. You can simply scatter about 3 cups of rinsed lava stone on top of the gravel.

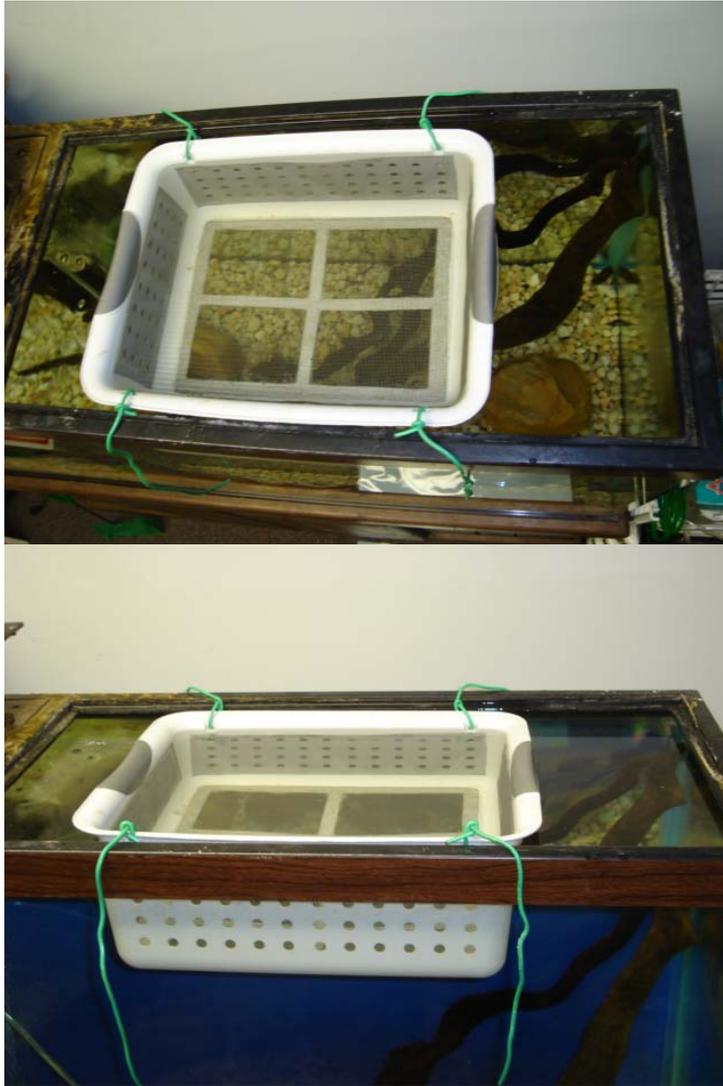

Don't buy a full bag as you will only need about 3 – 4 cups.

NOTE: Do not use any of the 100% silicon sealants found at any home improvement store to make the bio-board. While they may say they are 100% pure silicon, they may contain anti-fungal compounds that are guaranteed to kill your fish. It's worth the couple extra dollars to use sealant especially made for aquariums.

Making an Egg Basket

While using a commercially available egg basket is acceptable, you may find that the overall size and shape is both too small and too cumbersome when it comes time to remove diseased eggs. Additionally, the close confines of commercial egg baskets allow diseased eggs to transit fungus and bacteria quickly increasing the possibility of infecting all your eggs. An alternative egg basket can be made from a plastic storage container.

A how to video can be found on the Virginia TU You Tube Channel: <http://www.youtube.com/VACouncilTU>

Starting the Tank Set Up

Position the tank on the foam board (cut to fit the bottom of the tank with about ½” overhang on all sides). Cut the remaining foam pieces to fit the back, front, top, and sides of the tank. Attach the back and sides with duct tape. Some programs take this opportunity to have their art students draw a mural either on the piece of foam going on the back or paper that can be put between the tank and the foam insulation. Attach the front section so it can be easily removed for viewing of the eggs/fish during the day, but can be put back on at night.

Carefully add the rinsed pea gravel (approximately ½” and 1” deep, but do not pour it in) and lava stone bioboard at this time or scatter the lava stone across the tank bottom. Fill tank about half full of clean water. Clean buckets are best used for this purpose. Tap water can be used for the initial setup, as there will be no fish put into the tank within the next 24 hours. But later, when changing water in the tank, it must be “aged” to allow the

chlorine to dissipate unless you are using well water or adding a de-chlorinating solution. Chlorine will naturally dissipate within 24 hours. If tap water must be used in an emergency, a de-chlorinator solution should be added as directed. **Note: some schools especially in urban areas may have Chloramines instead of chlorine in the tap water. If this is the case you must use a dechlorination product to make your tap water safe for fish.**

Chiller connections. Now, install the pre-filter on the water pump intake opening. There are extra parts with the pump that are not necessary and can be set aside and saved. There will be a hose barb fitting provided with the pump for connecting the vinyl tubing. This is a hose barb on one end and a threaded connection that screws into the top of the pump. Place the clamp on the vinyl tubing. The vinyl tubing is then pushed down onto the hose barb and the stainless steel clamp is tightened to secure the hose to the fitting. This tubing will need to be cut to fit from the pump to the intake port on the chiller. Place water pump inside tank on the bottom.

The chiller should be positioned as close to the tank as possible to minimize any strain on the water pump. Find the best location for the chiller, one where it can be easily accessed for maintenance and temperature adjustments, but located out of the way of the tank (off to one side or below the tank works best). The following are generic instructions. Please follow your chiller specific directions for set up.

The vinyl hose from the water pump outtake is then connected to the chiller intake port. The vinyl tubing pushes down onto the port inlets, lubricating the inlet barb helps (use warm water). Push the tubing all the way onto the port and make sure it is well seated.

Aqua chillers require “elbow” barbs attached to the intake ports. The “IN” port is on the back left when facing the chiller. Use SS clamps on the tubing as necessary.

The last section of tubing returns the water to the tank. Use enough hose, about a 3-4 foot length, so it hangs across the back of the tank and can be tied down to the center support. The outflow tube should extend about 2” below the surface of the water, flowing in the same direction as the outflow tube from the filter. You will need to adjust the flow when you get your eggs so that there is not a direct current over the eggs.

Tighten all the tube connections. Install and tighten the hose clamps to prevent any of the tubes coming off accidentally.

Air Pump connection:

Place the small air pump behind the tank. Attach tubing from air pump then use scissors to cut line and add the check valve. The check valve will prevent water from returning to the air pump in the event of a power outage. Blow in the check valve to ensure you install it with the air flow direction coming from the pump. Run the tubing from check

valve to air stone. Air stone is very fragile and should be removed from package with knife or scissors. Plug in air pump and verify airflow to stone.

Now fill the tank with water to within 1 inch of the bottom of the black plastic lip of the tank.

Main Filter Pre Filter:

Cut the Aqua Clear foam block into 3 equal sections. Hollow out a hole the diameter of your filter intake tube and the depth of the slotted tube cover in one of the sections and insert the intake tube into the foam. **This pre filter will help keep your main filter cleaner, but it must be rinsed out weekly (in dechlorinated water) to keep the pre filter clean and allowing free water flow into the main filter. Additionally, it will prevent the Alevin or fry from getting sucked into the filter and becoming sushi!**

Water Filter:

The dual compartment water filter (Whisper 60) hangs on the outside of the tank; if you are using a Fluval filter, it can sit next to the tank or on the floor within close proximity of the tank. The filter can be located on the other end from the chiller and UVS or if space permits, it can be located on the same side. But both the chiller output line (if not using the Tradewind) and the filter outflow line must flow in the same direction down the tank. This way, there is a constant water flow across the tank and bioboard. Remove the filter components from their plastic bags and rinse them under running water. Place them in the filter compartments as directed in the manufacturer's instructions. Install intake and outflow tubes as per the manufacture's instructions. Install the pre-filter on the slotted part of the intake tube. You can cut the outflow flexible tubing (make it about 2" below the final water level) to length; the bottom of the intake slotted tube should sit about 2" from the top of the gravel.

For the Fluval filter, use the built-in primer pump to prime. You will hear air being forced out the outflow tube as the filter body fills with water. When the bubbles have stopped, the filter is primed.

The hanging water filter must be primed by pouring water to fill the compartments before plugging in the filter.

Plug in the main filter, submersible water pump, then the chiller and air pump into the power strip.

Section III. "Decorating" Your Tank

Now for the great debate on how your tank should look. In nature, trout live in streams that have rocks, plants, and sunken tree branches. Why not make your tank resemble nature? Besides being helpful to the health of the tank (which we discuss in a moment), it can provide your students with a look at the real habitat of trout – not a sterile looking tank.

We have already put gravel in the bottom of the tank to resemble the streambed, so let's complete the picture.

Plants

Plants provide a great habitat for beneficial bacteria. Additionally, they are another biological filtering agent. The easiest way to introduce plants into your tank is to weigh down the base of the plants with stream rocks or aquarium gravel. Recommended aquatic plants are:

- Anacharis can be found in most pet stores or pond supply places. It is an inexpensive plant and easy to obtain.
- Hornwort is also acceptable.
- **DO NOT RELEASE ANY AQUARIUM PLANTS INTO THE WILD**

If you need a plant supplier contact www.springdalewatergardens.com

Driftwood and Rocks

The introduction of driftwood and rocks into a tank will add a more natural look to your tank as well as introduce healthy bacteria to break down excess food and fish waste. Find interesting pieces of wood or rocks submerged in a stream. Make sure the wood or rocks have been submerged in the stream otherwise the wood will float and the rocks will have no bacteria growing on them. Do not dry or boil the wood or rocks, this will kill the good bacteria.

Please understand that, while the introduction of plants and driftwood will very slightly increase the tank cleaning time, the value of your students seeing trout in a “native” habitat greatly outweighs the additional time to clean around the plants and wood.

Other Fish and Crayfish

The introduction of other types of fish and crayfish are not recommended, they will eat your trout.

Section IV. Getting Ready for Your Eggs

During the summer, the Regional TIC coordinator will gather the information on number of tanks and type of trout eggs requested from all the chapter TIC coordinators. She/he will then coordinate with Jason Hallacher, VDGIF, as to which hatchery locations will provide the eggs and develop a preliminary delivery date and pick-up point for each school. When the school year begins, the chapter TIC coordinator will notify each teacher the details of their egg pickup date and location.

A definite pickup date at the VDGIF office in Verona will be established usually by late September.

The area coverage for egg distribution for this year will be as follows:

The Verona office of VGIF (517 Lee Highway, Verona) will handle the distribution of brook trout eggs and food for the area of Central and Northern Virginia defined as all locations NORTH of Route 460. This will include

Lynchburg across the state to Petersburg. IT DOES NOT INCLUDE ROANOKE. **All programs in this area will raise Brook Trout.**

For TIC programs in Roanoke and south, the TIC coordinators will need to coordinate a pickup date with Brian Beers, manager of the Paint Bank hatchery. If you are so inclined, a possible hatchery tour could be arranged if you want to make a field trip with your students. If you choose, you can also arrange egg pickup with either the Wytheville or Marion hatcheries

30-60 Days Before Eggs Are To Be Picked Up

1. Assemble all parts for aquarium setup (see suggested equipment list) and fill the tank with water.
2. Turn on the filter.
3. Start dosing your tank with Crystal Clear One Fix Bacteria as soon as your chiller is running on a weekly basis. (See Picture Below)
4. Make the egg basket(s) if you are not using commercially purchased baskets and Bioboard (if using).

1 Week Before Eggs Are To Be Picked Up

1. Turn on the chiller, setting the chiller thermostat temperature to register around 50 degrees. Please note - **you should always rely on your digital thermometer for an accurate water temperature reading.** After one day, read and adjust the chiller thermostat as required to have the water temperature register around 50 degrees.
2. Cover the sides and top of your tank with the foam board insulation (or cardboard)
3. Test the water parameters and record the reading on the results worksheet (see P. 50 for sample). Do not worry if the pH is around 8. (see Water Testing in the next section for more detailed information)

2 Days Before Eggs Are To Be Picked Up

1. Verify water temperature down to 50-52°F (10-11°C) - **rely on the digital thermometer, not the temperature reading from the chiller.**
2. Position the egg basket(s) in the tank. Make sure that the basket(s) are at the opposite end from the water flow. There should not be a strong direct flow of water directly on the egg basket(s).
3. The air stone should be placed near the egg basket(s), but not underneath them.

Section V. Raising Trout

Getting Eggs

- When you receive your 200 eggs, they will be in a mesh or cloth bag. Make sure you bring an empty water bottle when you pick up your eggs so it can be filled with water from the hatchery. That way you can pour some cold fresh water onto the eggs during the trip home keeping the eggs nice and moist. You should also bring a medium sized lunch cooler 1/2 filled with ice or ice packs, paper towels, and a small plastic sandwich container to hold the eggs. So, the order of packing is, the eggs will go into the small sandwich container with a small amount of hatchery water; then you place the egg container on a layer of paper towels covering the ice.
- Once you get to the school the eggs will need time to acclimate to the tank. Let the sandwich container you transported the eggs in float in the tank for about 30 minutes, adding approximately a ½ cup of your tank water every 10 minutes before removing the eggs from the terry cloth bag and pouring the eggs into the hatching basket.

Eyed eggs—(they spend about two weeks at this stage)

- If possible for year end results, count the number of eggs as best you can.
- Eyed eggs are identifiable by their characteristic dark spots – the trout’s two eyes.
- Any completely white eggs or eggs with white spots **MUST** be picked out. The white coloration is a fungus that spreads **REALLY** fast. Pick out spotted eggs twice a day if possible—especially as a last check on Friday afternoon.
- The outer shell must remain translucent. Uniform cloudiness can be okay, it might be just the trout development.
- An egg with any opaque spots (or fully opaque) will not develop.
- It is helpful to gently blow on the eggs using the turkey baster. Moving the eggs using this technique will help prevent fungus from growing on the eggs. Do this while your checking for dead eggs.

Hatching—(no more than 2-3 days from first egg to last)

- The eggs will not all hatch at exactly the same time. The eggs will hatch over about a 2-3 day period from the first egg hatching.
- Some eggs will not hatch properly and should be picked out after a couple of days.
- Alevins may not come all the way out of the egg.
- Any leftover eggs must be removed or isolated—these likely will not hatch).
- The leftover transparent shells float to the top of the tank or in the basket. Remove as many as you can. The rest of the eggs will break down and create a foam—this is normal. You can scrub the sides of the tank to loosen this foam.

Fry Stages

Just after hatching

- During this alevin phase you may see a jelly-like fungal growth. Check for this around the inside tank surfaces. Also check for this growth on the surfaces of the

hatching basket. If you find this, wipe or scrape the surfaces with a sponge or other tool.

- Loosening this growth will send it through the filtration system.

Alevin (sac-fry)—(1-3 weeks)

- Look for your odd trout (two-head, three-head, etc.). This is a good lesson in survival of the fittest—these odd trout don't usually survive until release.
- Look at heart development, etc.
- Alevins can survive in a Petri dish under a microscope or hand lens for a short period of time (2 to 3 minutes) if you want to let your class observe the Alevins more closely.
- Dead alevins will turn white just like the eggs, remove them at least twice daily

Swim-up stage— (one week or less)

- As yolk sacs disappear, some trout will start swimming along the bottom of the basket. Eventually they will swim up off of the bottom of the basket. This will happen gradually. It is now time to start feeding the trout. Keep the trout in the basket, this allows them to easily find food.
- To feed, put a small pinch of starter food near the swimming fish (in basket or otherwise). The trout will sometimes ignore the food at first or miss it. This is fine; they will figure it out in a day or so. It also helps to swirl your finger around the basket to make the food sink down to the waiting trout.
- Some trout never learn to feed, and will die. These non-feeding fish are called “pinheads”—big heads, little bodies. These trout should be removed, as they will not develop.
- Every TIC classroom sees a mortality spike with the pinheads—it is VERY normal.

- Be sure to suck any old food off the bottom of the basket with the turkey baster and discard it.
- If your trout get out of the basket be sure to turn off the filter system for a few minutes when you are feeding the trout for the first couple of times. Not having a strong current will make the food more visible and more likely the trout will begin to feed. **MAKE SURE YOU TURN THE FILTER BACK ON!!!!!!**
- Once all fry are swimming up and have been eating for at least 2 weeks, it is time for the next step.
- Unhook the basket(s) and gently pour the trout into the tank.
- You can now remove the basket(s) for the year.
- **MAKE SURE ANY WATER INTAKES ON PUMPS OR CHILLERS ARE COVERED WITH THE AQUACLEAR FLOAM BLOCK. IF YOU DO NOT COVER THESE INTAKES THE TROUT WILL GET SUCKED INTO THE PUMP OR FILTER!**

Fry stage—(6-8 weeks)

Feeding less more often is a better method for feeding.

- Continued leftover food means that you are overfeeding your fish. Overfeeding can cause problems with ammonia and nitrite levels. If in doubt, feed less until you are fairly certain the fish are eating everything you are feeding them.
- Look for parr marks on the trout – the vertical stripes. Additionally, as they get older, some of the adult coloration will start to appear.
- Vacuum the bottom of the tank once a week using the gravel cleaner.
- Always keep track of your water chemistry. If any levels seem too high, do a big water change (20% or more). Be careful to watch the temperature as you do this. Don't let the tank temperature fluctuate more than 5 degrees or so. In an emergency, clean water is more important than temperature stability, though.
- Cannibalism can occur—the big fish do eat the little fish.

Section VI Feeding Instructions For Free Swimming Trout

Once the trout are out of the egg basket they should still be given small amounts of food. Over feeding the fish can pollute the tank environment. Having said that, you do want your trout to have fat, round stomachs (see the picture below). I usually feed a 1/8 tsp of food per day, 1/16 tsp in the morning and 1/16 tsp in the evening. Use your best judgement, and feed more if they look skinny and less if a lot of the food falls uneaten to the bottom of the tank. Trout are wild animals and they can survive over a weekend without any food, but during vacations it is best for someone to check on the tank and provide a small amount of food on a regular basis if you are not using a weekend feeder. If you plan on letting helpers feed your fish while you are on vacation, it is a good idea to measure out your food ahead of time to avoid over feeding.

NOTE: IF YOU RUN OUT OF TROUT FOOD YOU CAN USE TROPICAL FLAKE FOOD OR PELLETS FROM ANY PET STORE. JUST MAKE SURE TO USE SMALL PELLETS SO THE FISH CAN GET THEIR MOUTHS AROUND IT.

Section VII. Water Quality

Raising trout can be tricky, but keeping the tank system clean and keeping the tank bacterial colonies happy will greatly increase your chances of success. The best way to do this is by adding your weekly dose of Crystal Clear One Fix and performing water changes. Fish eggs and alevins produce very little waste, so water changes are usually not necessary until you start to feed your fish. However, if you have an ammonia or nitrite spike at any time you should perform a weekly 20% water change using aged tap water (at least 48 hours), dechlorinated water or well water. Also increase your dose of Crystal Clear One Fix to three times a week until your ammonia or nitrite readings return to normal. If there is slime or algae on the walls of the tank, clean it off with a sponge on a long handle. You can also agitate any precipitate and allow the filter to take in the debris.

The Nitrogen Cycle

The nitrifying bacteria in the tank (Nitrosomonas and Nitrobacter) change trout waste and excess food (ammonia) into nitrites and then further into nitrates. While ammonia and nitrites are toxic to the fish, nitrates are not very toxic at all. The nitrifying bacteria are surface dwellers. They live on all the surfaces of the tank and equipment, and especially on all faces of the gravel, lava stone, and wood. Crystal Clear One Fix is a concentrated bacterial solution that kick starts this cycle. Make sure to use it weekly!

How to Perform a Water Change:

Water changes should be done with fresh clean water, no chlorination. “Aging” your water by letting it sit out in jugs or buckets for at least two days will allow the chlorine to dissipate (well water does not need to be aged) or you can use a dechlorinating solution to have your water ready immediately. **Note: some schools especially in urban areas may have Chloramines instead of Chlorine in the tap water. If this is the case you must use a dechlorination product to make your tap water safe for fish. Make sure your tap water conditioner specifically states that it removes chlorine and breaks down chloramines.** Prime and use the Gravel Vacuum according to the manufacturer’s instructions. Make sure you have a large enough discharge bucket – a 5 gallon plastic bucket should suffice. Siphon through all the gravel on the bottom of the tank. Watch as the fish waste and excess food moves up the siphon; once the siphon is clear move through the gravel until you find more debris and repeat the process until you have

removed about 20% of the tank water. Once you start to feed the fish cleaning the tank once a week will be more than sufficient. When you have finished cleaning the gravel, add new dechlorinated water to the level it was before cleaning. Add the water slowly, trying not to create a disturbance. Additionally, wring out the chiller and filter pre-filters once a week in dechlorinated water to remove the surface crud and waste. Make sure you record your water changes in your daily log. Use common sense with water changes. If you're not seeing a lot of "dirt" coming out of the gravel while you siphoning and the water chemistry looks good, then you can probably cut back on your water changes.

Imbalances in ammonia or nitrites indicate that water changes should be increased. If fish behave strangely or start dying in large numbers, poor water quality is often the root of the problem. If an emergency water change is needed, no more than one third of the water should be changed and it should be chilled close to the correct temperature before addition by floating ice containers (see Q and A section for details).

Water Testing: *Use Kit provided with set-up*

The test kit provided has solutions for testing for ammonia, nitrate, nitrite, and pH. While testing for all four is a good practice, the three key tests are for **pH**, **Ammonia**, and **Nitrites**. All test results should be kept in a log on a daily basis for review as well as providing "real" data for the students to graph. **If your pH reading is 7.6, use the HIGH pH test chemicals as you may be at the upper limit of the lower pH chemical test solution.**

pH: Depending on your water source, you will have pH readings from 5.0 to 8.0. In the ideal world of raising trout, you should strive for a pH reading of about 7.0. **However**, tests done during TIC trout releases have shown that stream water pHs vary from 7.0 to 8.0. **As long as the pH stays fairly constant, usually within 0.3 of the base reading you took when you established the tank, your trout will be fine.** Do not worry about having too high a pH unless you get into the 8.3 or higher range. If you get a pH reading above 8.3 or below 6.5, contact your TIC coordinator quickly.

The following are instructions on how to naturally raise or lower the pH in your tank if the pH reads above 8.3 or below 6.5 if you don't want to add chemicals to your water.

If the water is too basic (above 8.3), gather about 2 or 3 handfuls of **OAK** leaves and put them into a mesh bag or stocking. Let the bag float in the water or weight it so it sinks. The tannic acid in the leaves will naturally lower the pH. You may have to replenish the oak leaves after a couple of weeks.

If the water is too acidic (below 6.5), usually adding a total of ½ cup of rinsed coral chips in a 55 gallon tank will raise and maintain a pH of about 7.0 depending on the existing water chemistry. Aquarium hobbyists have used coral chips for many years in lieu of chemicals that are on the market. As with anything that alters the chemistry of aquarium water, it must be done in slow steps in order not to adversely affect the fish. Divide the ½ cup of chips into 3 equal

portions, spreading a portion every 3 or 4 days across the bottom of the tank over a 2 to 3 week period. If at the end of the 3rd week, if the pH is still lower than required, add another 1/2 cup of rinsed coral chips over another 2 to 3 week period. Coral chips can be found in most pet stores.

Using coral chips exclusively instead of gravel will result in a pH off the measurement scale and will be harmful to the development of the fish.

DO NOT ATTEMPT TO MOVE THE pH level more than 0.1 or 0.2 IN A DAY.

Ammonia or Nitrites: Major water changes will be needed if the ammonia or nitrite loads become consistently too high for the biological filtration to handle. This usually occurs when the fish are over fed, the tank is not cleaned on the suggested schedule, or there are too many fish in the tank and the bacteria colony has not been fully established. If the problem is frequent, some fish may need to be removed to reduce the daily levels or the number of weekly water changes increased to 3 or 4 a week. Increase your dosage of Crystal Clear One Fix to 3 times a week (or daily in dire circumstances) to add additional bacteria to convert ammonia into harmless compounds. Fairly quickly, your ammonia readings will drop to 0.0 or 0.1. The nitrite readings will also drop and you should start seeing nitrate readings as the bacteria convert the nitrites to nitrates. Your ammonia and nitrite readings should stay down as long as you keep the gravel clean by siphoning and resist over feeding the fish.

Daily Check List:

1. Keep an eye on tank temperatures; an increase in temperature might indicate a chiller problem.
2. Remove any dead eggs, alevins, or trout.
3. Feed trout (after they have hatched).
4. Test the water parameters (Ammonia, pH, Nitrites, and Nitrates) and record the readings in a log. Also enter any water changes and other events into the log.
5. Ensure that water is flowing from the chiller and the filter and that the air stone is still working.

Weekly Check List:

1. Clean the gravel (After you start feeding the trout).
2. Add 5ml of Crystal Clear One Fix Bacteria
3. Remove and clean the pre-filters by squeezing them out in a bucket containing dechlorinated water.
4. Check all hose connections and tighten if any are loose.

Bi-Weekly Check List:

Remove dust and lint from the fins of the coolant tubing (those black thin metal slats on the side of the chiller). This can be accomplished using a small vacuum cleaner, dusting cloth or soft bristle plastic dust brush.

A Note About Enthusiastic Help:

Every year, many schools enlist the assistance of security and maintenance staff to feed the fish on the weekends and holidays. These well-meaning helpers, often become great fans of the fish, and are soon spending their break periods watching...and yes...feeding the fish. People with different schedules, feed the fish unaware that others are doing the same. You might not want to just warn these fans about over-feeding, but have a sheet of paper near the tank so they can track how often the fish have been fed. Make sure to pre-measure the food so your help doesn't over-feed your fish.

CRISIS NOTES—READ BEFORE TROUT TRAGEDY OCCURS

- Always have buckets waiting with tank-ready water - dechlorinated by sitting 48+ hours or use a dechlorinating solution for instant readiness). If you come in and all fish are lethargic – **do a 20% WATER CHANGE every day for 2 or 3 days.** Skip feeding for a day or two.
- If you come in and all fish are unmoving at the bottom of the tank – **do a 20% WATER CHANGE every day for 2 or 3 days.** Skip feeding for a day or two.
- If you come in and your fish don't respond to food – **do a 20% WATER CHANGE every day for 2 or 3 days.** Skip feeding for a day or two.
- During the first few weeks after the alevins hatch, initial ammonia and nitrite spikes from overfeeding are likely until the bacterial colony is established. During this time, water changes will help decrease your ammonia and nitrite readings. Also increase your dosage of Crystal Clear One Fix to 3 times a week. **DO NOT ADD ANY CHEMICALS THAT CLAIM TO NEUTRALIZE AMMONIA. WHILE IT WILL NEUTRALIZE THE AMMONIA, IT WILL ALSO ROB YOUR GOOD BACTERIA OF THE FOOD IT NEEDS TO GROW.**

Other Helpful Notes

- All water in tank must remain extremely clean. Everyone **must** rinse hands of all contaminants including lotions, soap, etc, before working with tank.
- If chiller runs continuously, contact your TIC coordinator, as it may need more refrigerant or insulation.
- **Have about 6 – 8 frozen 2 liter jugs of dechlorinated water on hand. In the event of a power outage, float one or two of these at a time in the tank to keep temperature down. All labels and glue should be removed from jugs before use. In an emergency, ice cubes in a zip lock type of bag can be used.**

Section VIII. Vacation Notes – If Not Using Weekend Feeder

Prepping for short vacations (3- or 4-day weekends)

- Feed less on Friday.
- Do your water change as normal.
- They will be fine.

Prepping for mid-length vacations (7-10 days)

- Trout are wild animals that can survive leaner times. They do not need to be fed or visited during a 10-day vacation.
- Continue with the normal feeding cycle in the days leading up to vacation.
- If anything feed a little less, so as to minimize ammonia discharge during holidays.
- Do a nice BIG water change on the day you are leaving. If you can, do one that morning and one that afternoon. Otherwise, just do a big one! Be careful to watch the temperature as you do this. Don't let the tank temperature fluctuate more than 2 or 3 degrees or so.

Prepping for LONG vacation (11+ days)

- Same prep as above.
- Plan to come in once to feed, if possible, about halfway through if not using the automatic feeder.
- If you can't come in, don't worry. Trout are wild animals that can survive the lean times.

Weekend and Vacation Notes – If Using Weekend Feeder

- Some of you may use a weekend feeder to feed your trout over weekends, holidays, or vacations. Follow the directions for loading the food into the system and setting the food dispensing time.
- Test the system to make sure it is dispensing the correct amount of food. You may have to adjust the dispenser depending on the model you have.
- Set the system to dispense only **1 / 2** the amount of daily food you would normally feed. This way, you reduce the possibility of uneaten food polluting the tank.

Section IX. Crisis Mode

What if I come in and many of the trout have died? What do I do?

- Remove healthy fish first by putting them into in a reserve water bucket with the emergency ice blocks, no matter its temperature.
- Put a battery-operated aerator or tank's air stone in the bucket.
- Make sure your water temperature is in low 50's and that your chiller is running properly
- Test your water for ammonia and nitrites
- Siphon the gravel and change 50% of the water out of the tank.
- Leave pump and filter intake covered.
- Clean tank with clean scrub sponge and gravel cleaner. Remove as much crud as possible.
- Refill tank with any water available (if using chlorinated tap, use a declorinating product).
- Cool water with ice or freeze packs.
- Drain and clean the filter and pre-filter and turn it back on.
- Add Crystal Clear One Fix as soon as possible.
- Replace fish in tank when water is chilled back down to the low 50's.
- The next day, add more Crystal Clear One Fix. Continue daily for one week.

What do I do if my chiller stops working?

Contact your TIC coordinator ASAP. Float 1 or 2 of the frozen jugs of water on hand in the tank to maintain the temperature. Replace as necessary until your replacement chiller arrives. All labels and glue should be removed from jugs before use.

Obtaining an Emergency Replacement Chiller Procedure

Dr. David Jones of Martinsville has graciously offered to maintain a supply of chillers in the event an unexpected chiller failure. He is willing to overnight a chiller in order to keep the tank operating properly.

If you experience a chiller failure, call Dr. Jones at both of the following numbers:

Cell: 276-634-8488 Office: 276-638-8888

When you talk to him, you will need to provide him with:

1. Your name, address, phone number, and TU chapter name; and
2. The shipping address where you want the chiller sent.

You will also have to get the address where to send the check for the cost of the shipping and the replacement chiller.

The school, if not supported by a TU chapter, will be responsible paying for the cost of shipping this replacement chiller to the school as well as the cost of a new chiller. Dr. Jones has indicated that the chapter or school may take up to a year to repay him, by check, for the cost of the chiller and shipping.

Section X. Trout Release and Transporting Techniques

The materials you will need are:

1. Sturdy cooler or bucket (clean cat litter buckets work well) with a loose-fitting lid.
2. Ice made with dechlorinated water in a Ziploc bag or 2-liter bottle with labels removed.
3. Battery-powered air stone – if travel time is over 45 minutes.
4. Lava rock from the tank – if travel time is over 45 minutes.

Instructions:

1. Fill cooler or bucket half full with water from tank (be sure you can lift the cooler). The reason for filling only half way is that the introduction of air into the water is more important than the depth of the water. The slight jostling of the water in the bucket/cooler will keep adding oxygen to the water.
2. Put the lava rock from the tank into the bottom of the cooler.
3. Transfer trout fingerlings to cooler or bucket using a small net.
4. Add ice to water -- but monitor the temperature, do not allow it to drop too low. Try to maintain temperature within 5 degrees of tank temperature.
5. Insert and start air stone – if used.

Hints:

1. Make sure the trout aren't in the bucket or cooler longer than they have to be.
2. Make sure to have enough water, but not so much that the cooler can't be carried.
3. Make sure the lid is on tight enough so that your fingerlings don't splash out, but don't seal them in and cut off their air supply.

NOTE: Whenever releasing fish into ANY body of water, you must have state approval to do so. If released into the wrong body of water, our small fingerlings can permanently alter an ecosystem. Please coordinate your trout release with your TIC coordinator for more information. No plants or creatures should be released into the stream.

Once you've arrived at the stream or second tank, it is important to slowly acclimate your fingerlings to their new environment. Monitoring the temperature of your cooler or bucket, slowly add water from their new stream/tank, one or two cupfuls at a time every 10 minutes. The goal is to gently change the temperature and water chemistry of your cooler or bucket water to near the temperature and parameters of the new water, allowing the temperature to change no more than a few degrees every ten minutes. Once the bucket/cooler temperature is within one or two degrees of the stream/tank temperature, remove the fingerlings to their release container. To release the trout, lower their container into the stream/tank and gently tip it to let them out. You can either release

them that way or you can transfer them into individual cups so each student has one to release.

Section XI. End of Year Cleanup

At the end of the TIC season, it is important to clean your aquarium set-up in order to ensure a successful next year. If you take a few minutes to make sure everything is clean, your equipment will have a much longer life. Here are a few pointers for cleaning the various components of your system:

Aquarium Tank

1. Turn off the electrical pumps, chillers, filters, etc. Empty the tank almost all the way, by your usual method--many people like to use the gravel cleaner to do this work. Then remove the gravel, wood, and plants.
2. Finish emptying the tank and disconnect the tubing.
3. Using a solution of 1 part Chlorine bleach (Clorox – unscented) and 10 parts water, wipe down the interior and exterior of the tank. You can also use a 1 part white vinegar to 5 part water solution. A soft sponge (dedicated to this use only) can be used to scrub hard to remove scale and algae growth. For stubborn scale/algae, you can scrape them off carefully with a straight edged safety razor.
4. You can use the same solution from above for cleaning out the tubing (clean tubes using long brushes you can buy at any pet shop).
5. Rinse the tank to remove any chlorine/vinegar and wipe dry with clean cloth, or let air-dry.
6. Wash and dry the gravel and wood by laying out on a cloth or towel in the sun or a ventilated area. The gravel can also be sterilized with the Clorox/vinegar solution, but they also MUST be rinsed and completely dried. Do not use either solution on the wood
7. Put the gravel and wood inside the tank and store it in a safe place covering the top with any dust-proof covering.

Aquarium Chiller

Drop-in style chiller (Tradewind)

1. Using a bleach or vinegar solution and a dedicated sponge, you can wipe off the exterior of the drop-in unit.
2. For hard-to-remove plaque, a small PLASTIC scrub brush can be used. NEVER USE A WIRE BRUSH.
3. Remove dust and lint from the fins of the coolant tubing (those black thin slats on the side of the chiller). This can be accomplished using a small vacuum cleaner, dusting cloth or soft bristle plastic dust brush. Your chiller will run more efficiently if you clean the lint and dust from this side of it.

Flow-through style chiller (Arctica Titanium, Prime Tower, Polar Bear)

1. Discard pre-filter sponge on pump.
2. Tip chiller and drain. Using pump or faucet hose, flush chiller with clean tap water in each outlet, to ensure any dirt is washed out of the cooling tank. Then tip further to ensure it is fully drained.

3. Remove dust and lint from all vents on the chiller, using a small vacuum cleaner, dusting cloth, or soft bristle plastic dust brush

Filter

1. Take apart your filter and scrub out the plastic parts with your 1:10 bleach solution or 1:5 vinegar solution.
2. Thoroughly rinse out all filter media (filter sponges, charcoal, ceramic cylinders, etc.) with regular water, and dry them in the sun or a well ventilated area. Scrub the ceramic cylinders until free of all debris. For the hang on type filters, it is recommended that you buy new filter cartridges for the following year. You can also use this year's filters that you rinsed out. Fluval filters do not need replacement parts – except for the pre-filter.
3. Thoroughly air-dry entire filter apparatus.
4. When all components are dry, re-assemble the filter and store inside the tank.

Section XII. Q and A's

My chiller temperature reading and digital thermometer are showing different temperatures. Which should I use? Always rely on your digital thermometer to determine the temperature of your tank. Chiller temperature readings can be off by as much as 10 degrees.

I set my chiller temperature for 55 degrees, but the digital thermometer shows 60 degrees. What should I do? Determine the difference in readings (in this case 5 degrees). Lower the chiller temperature setting by this differential and check the next day.

Are leaks a problem? How can I prevent leaks?

Once a chiller system is assembled, it is unlikely that a leak will develop. However, physical contact with the system could damage connections, particularly tugging on tubes. For this reason, students should not touch chiller or filter hardware without supervision. A serious leak will pump the entire contents of the tank onto the ground within a very short time.

What should I do if my chiller system starts to leak?

If there is a leak in any external part such as the tubes for the chiller, turn off and unplug all electric tank systems. A large volume of water may be contained in the chiller and chiller tubes, so it might help stop a leak if the tubes are removed from the tank and placed in a 5 gallon bucket. It is important that the leak be fixed as soon as possible so that the chiller can continue to keep the water cool. Float some frozen tank water or ice in a zip lock bag in the tank to maintain the temperature while you are fixing the leak.

Can I fix leaks on my own?

The assembly of the chiller system is straightforward, so fixing it is quite possible without assistance. Simply unscrew the connection, and make sure that it is not cracked or damaged in anyway. Next, reassemble the leaking connection carefully. You can use a

tool to tighten any connection, but do not force any plastic parts as they will crack under excessive strain.

What happens if there is a power failure? How much time do I have?

It is important that the fish have a stable a water temperature as possible. Short downtimes, of an hour or two at a time, probably will not harm the fish or change tank temperatures by any great amount. However, lost power during the night or over a weekend (or worse still, a long vacation) will likely be fatal to the fish.

What should I do if the power must be turned off?

All individuals such as custodians, who may turn the power on and off, should be informed that the trout system needs constant power. If there is no way to prevent it, for construction for example, it would be best to cycle the power. This means running the chiller for two hours on, then two off. This is better than simply letting the tank sit all day without power.

Can I keep eggs or fish in a household refrigerator?

Refrigerators are not an acceptable substitute for the tank environment. Because most refrigerators operate between 35 and 40 degrees, they are far colder than the tank.

What do I do with my eggs or fish in an emergency?

In an emergency, eggs can be preserved by placing the hatching basket in a container of water and putting that in a cooler in a cool dark place, with an ice pack and thermometer. Careful regulation in the amount of ice should make it possible to keep the eggs around 50 degrees. Do not add ice to the eggs directly; apply to the outside of the egg container. Ice water may be dirty, and the rapid melting from immersion would cause sudden temperature changes that might do more harm than good.

With fish, particularly large fish, the only option in an emergency is to add ice to the tank. The best way to do this is to freeze large plastic containers of water, such as soda bottles with the labels removed, and add them to the tank. When creating these, do not fill them to the top as the ice that forms takes up more space than the liquid. Clean ice packs can also work. It is possible to regulate temperature by adding or taking away ice in this way. Do not add regular tap water ice cubes directly to the tank unless they are in a Zip Lock type of bag--this ice likely has chlorine in it, which can harm the fish. Some teachers create tank-water ice cubes, in anticipation of an emergency.

A 5 gallon bucket for every 20 fish would be a good choice for holding fish in an emergency, if there is a problem with the tank.

It is best to prevent any such problems and carefully maintain the tank environment. The priority in an emergency is getting the tank environment back to normal; no emergency procedure can replace the stability of a working tank.

What should I do if there is a serious leak while I am away, and the tank is almost empty when I return?

If there is a serious leak, during the night or weekend, almost all of the tank water may be pumped out. It is unlikely for the tank system to fail on its own, but it is important to be ready in the event of such an accident. If the fish are in very shallow water, and the

chiller is no longer working because the pump is running dry, it is important to carefully repair the tank system environment. First, you should find and fix the leak. Unplug the filter system. Next, add a declorinating solution to a container holding about 5 gallons of cold tap/well water (stir the tap water as you add a declorinating solution; for well water this step is not necessary). This should be enough to get the chiller working again; if it isn't, add another 5 gallons of cold declorinated/well water to the tank. Add this water slowly, and try to make this water around the same temperature as the tank water (which might be warmer by now). Make sure the air stone is working and putting bubbles into the water.

Once there is enough water for the chiller to run, you should let the tank reach 50 degrees again. Open the filter and pour all the water out of it and rinse the filter media. Because there was no water circulation, the filter will be full of dead bacteria that will kill the fish.

At this point, use a declorinating solution to get as much tap water as possible (you don't need this solution if you are using well water) in every clean container you might have. Put your emergency ice packs into the containers to start lowering the temperature. Once the declorinated/well water has reached a temperature close to the tank's temperature, slowly add the water to the tank. If you can, it would be best to add only a few cups at a time, many times during the day. Continue to do this until the tank is about half full. Open the filter, refill it and add a dose of Crystal Clear One Fix, reconnect the filter system, and plug it in. Once the tank is half full, you can add the aged water a few gallons a day. Continue to make new aged water as you use it until the tank is back up to normal levels. Then resume normal maintenance procedures including water changes.

The idea throughout this process is to make the changes for the trout as subtle as possible. Large swings in temperature and/or water quality can stress them out and increase mortality.

How can I inform custodians, or other teachers, about what to do if there is an emergency while I am away?

It is a good idea to give custodians some basic information about the requirements of your tank. For example, it is important that custodians know that your tank always needs electricity. It would be most helpful to place a sheet of paper (in a visible location) describing emergency procedures. This might include contact numbers, and basic advice on what to do to stabilize the tank if there is a chiller failure, leak, or power outage. You should prepare several frozen soda bottles of water to use in a chiller emergency, and then include the location of this ice and how to use it in your emergency procedure sheet. An example is below:

Tank Emergency Procedure:

In the event of a power outage, leak, or refrigeration system failure, or any other tank problem, please contact me: _____

Phone number: _____

If you cannot reach me, please try calling:

Contact: _____

Phone number: _____

Then,

In the event of a power outage: The trout in this tank need cold water to survive, and the chiller next to/under the tank maintains their temperature. If possible, the electricity to this tank should be turned on again. If the electricity must be off because of maintenance or construction for more than a few hours, please contact me as soon as possible. If I cannot be contacted in time, please place the frozen soda bottle of ice, located _____, in the tank to help keep it cool. Even with the ice, the tank needs electricity as soon as possible.

In the event of a serious leak: A serious leak can be stopped by turning off all electrical parts of the tank system, or unplugging them. Any leaking tubes should be placed back in the tank or in a bucket. After all the water is cleaned up, the source of the leak can be fixed. This will probably be loose tubes or tubes which fell out of the tank. If there are more than 4 inches of water left in the tank, the fish can survive. Please do not add any water to the tank if this is the case. Lots of tap water, or water that is too warm, can kill the fish. If there is very little water in the tank, please add only enough cold tap water to let the pump work again. If the leak is fixed, please turn on all devices before you leave.

Do I need goldfish to start my nitrogen cycle? If I start late, should I use more goldfish?

At this time, it is no longer recommended that goldfish be used to help “break in” the tank system. All systems should be installed with additives such as Crystal Clear One Fix which help create a suitable water environment.

Can I mix species of trout?

No, the different trout species may not be compatible. The risk of cannibalism among young fish (under ½ year of age) is greatly increased with species mixing.

Why are so many of my eggs, alevin, or fish dying?

Death is a natural part of fish development. Everyone should expect to lose eggs, alevin, and fish. The exact survival rate is highly variable and based on many factors. A sudden spike in mortality can indicate a tank problem. It is also worth noting that there are two naturally high-mortality periods, first during the egg stage and then again when the trout first learn to feed. Some fish never learn to feed and simply starve.

What is a normal death rate?

Death rates are different from one stage to the next. With eyed eggs, about 25-30% is expected to die. The loss of most of your eyed eggs does suggest a problem. As the fish hatch, and age further, survival rates should improve. By the time fish are free swimming and have learned to eat, death should be an uncommon event. Losing many free swimming fish, above all else, is a sign that the tank environment is not healthy. As they grow, fish produce more waste, so cleaning and water changes may be needed more often.

What do I do with dead fish or dead eggs?

It is very important that dead eggs, dead fish, and decaying waste matter (discarded food for example) are removed as soon as possible. This should be done at least once a day, and even more often during critical periods or as needed. This process alone is very important in keeping the remaining fish alive. Poor cleaning is very often the root cause of excessive fish death.

Why are my fish or eggs dying at an abnormally high rate?

Poor water quality, as a result of insufficient cleaning or lack of good bacteria is among the most serious threats to fish health. Once you start feeding it is essential that water changes of 10-20% per week (more as the trout get older and bigger may be needed) be maintained, with aged tap or well water. Other causes of fish death might be temperature fluctuations, lack of aeration, and chemical exposure. High ammonia or nitrite concentrations can result in sudden fish death. Your daily water testing will show if you are having continually high ammonia or nitrite concentrations.

How sensitive are the fish to temperature changes?

For best results, the trout should be exposed to the most stable temperature possible, as close as possible to the ideal. Fish can handle small fluctuations of one or two degrees, but sudden changes of almost any scale will be stressful. Changes of 5 degrees or more are a serious threat to trout survival particularly if they are sudden.

How can I help keep a stable tank temperature?

It is important that the chiller always be on and set to the appropriate temperature. Also, because water changes introduce warmer water into the tank, please limit these changes to approximately 10 – 20% of your tank volume at any one time. If you want, you can pre-cool your water by floating frozen bottles in the bucket before you add it to the tank. The use of insulation will help the chiller maintain a stable temperature, but may not be needed. Larger tanks will also help protect fish because they have more water to buffer any changes.

Why is the air stone needed?

Aeration of the tank is an important part of simulating a stream environment. The stream environment is not only cold, but also constantly moving and constantly mixed with air. Because of this, it is important that filters, air-stones, and the chiller pump all operate well. The pre filters on the chiller pump and the intake on the tank filter, as well as the surface of the air-stones should all be clean and free of debris.

Should students wash hands *before* touching tank water?

Students may wish to clean their hands before working in or around the tank **without using soap**. Simply use warm tap water for this, and for cleaning of other objects like nets and the bucket. This will help keep chemicals and dirt from getting into the tank. Moisturizers and other skincare products might also harm fish. It is very important that no soap enter the tank environment, because soap may harm or kill fish even in small concentrations.

Should students wash up *after* contact with tank water?

Yes. While tank water is not particularly hazardous to students, they should clean their hands with soap and warm water. Please do not use soap until all tank work is done.

Some of my hatched fish are not eating - Some of my fish are deformed. Is this normal?

Yes. During the growth process, some fish will die. Some fish may survive initially only to die later because they never begin to eat. Other fish will be deformed, and very often will also die as a result of this. This is a natural part of fish reproduction. It is not normal, however, for very many or most of the fish to die. If this is the case, there may be a problem with the tank environment.

My fish have hatched, what should I do with the eggs?

The discarded egg shells should be removed and disposed of.

When should the trout be allowed out of the hatching basket?

It is generally agreed that trout should remain in the basket as long as possible, even after some start to jump out on their own. Once the trout are feeding for at least two weeks, you can release them into the tank.

How do I let the trout out of the basket when it is time?

You can gently remove the basket from the sides of the tank and slowly lower it to the bottom of the tank. You can let the trout swim out from here. This allows some trout to remain in the protection of the basket for a few days. You may also gently tip the basket as well to remove them, but it is best to be as gentle as possible. Please make sure that the basket is empty before removing it from the tank. Using the pre-filters on the intake lines of the filter and chiller will ensure that small fish are not sucked into these units as a result of the powerful suction these tank components generate.

My alevins are very active, and are pushing other fish into the corners of the basket. What does this behavior suggest?

This type of activity is normal in trout. In this stage, young trout prefer dark corners. It may be helpful to put some screen material over the basket to reduce the amount of light these fish are exposed to. UV light can be harmful to eggs and alevin. Fish at this age do not need food at all. When beginning to feed, at the end of the alevin stage, please start with small amounts.

Trout are being sucked into the filter, how can I prevent this?

Using the pre-filters on the intake lines of the filter and chiller will ensure that small fish are not sucked into these units as a result of the powerful suction these tank components generate.

What is an ammonia spike? What can I do about it?

An ammonia spike is one example of a chemical imbalance in the tank environment. These are serious threats to fish health. The tank filter and its bacterial population help reduce problems like this, but they cannot work alone. The best way to prevent any chemical imbalances in the tank is to regularly clean the tank, and change the water. All debris such as food, waste, and dead fish should be removed as soon as possible. Water changes of 10-20% per week are required and should not be skipped. There is no replacement for regular cleaning and water changes. Also be sure to add Crystal Clear One Fix once a week. Setting up your tank 30-60 days ahead of time will prevent ammonia and nitrite spikes.

Can I use ammonia removal grains to prevent ammonia spikes?

We recommend that you avoid using these products. Add more crystal clear one fix instead.

My tank is coated with a green slime. What is this? What should I do?

Green films or slime may indicate algal growth. This will not necessarily hurt your trout, and some teachers leave it growing as it is beneficial to your good bacteria. Many, however, choose to remove algal growth. It can be mechanically cleaned by using an aquarium (or soap free) sponge or similar tool. Also, to prevent further algal growth, it is best to limit the amount of light entering the tank. The use of foam or paper to cover the sides of the tank will help. The tank should never be in direct sunlight at any time.

I am using the same tank system I had last year, what do I need to do to make it ready this year?

At the beginning of each year, to prepare for the next set of trout, you should clean all parts of the tank system with warm water. Please do not use soap on any part of the tank. If you are using a hang on the tank type filter, you should replace any disposable filter parts; Fluval filters do not require replacement filters. See our End-of-Year Cleanup Section XII for more information.

The water in my tank is cloudy. What should I do?

Cloudy water probably indicates an excess in decaying matter. This may be from dead fish, leftover food, or a problem with the filtration. Doing regular water changes, as well as cleaning the tank of all solid material, is the best way to fight this. Make sure the filter is functioning properly, and that water is flowing out of it. Clean filter components if needed with aged or well water, but do not use soap or any chemical cleaners. Carbon filter packs should be replaced every year. If fish are not eating all provided food, you may reduce the amount given until they are able to eat it all. Excess food after 10 minutes should be removed and discarded. Crystal Clear One Fix may be increased to 3-5 times per week.

How should I conduct water changes? What is the right amount of water to change?

Water changes are an important part of tank maintenance. Improper water changes can cause fish stress or even death. It is best to change about 10-20% of tank volume every week with tap water aged for more than 48 hours (so that the chlorine in the water has had time to dissipate), water treated with a dechlorinating solution, or well water. Chloramines must be removed using a dechlorinator.

Using the gravel vacuum is an efficient way to clean both the tank and remove water at the same time.

What happens to the fish next?

The fish will be released into a watershed stream or river. Students can participate in the transportation of fish to their new habitat as well as the release process. It is hard to determine the survival rates for released trout, but full grown fish have been recovered and genetically linked to trout raised in the classroom. However, in general, TIC is not a stocking program, but rather an educational program. The true value of raising and releasing trout lies in the process.

Hardware assembly FAQ -- also see our Basic Set Up page

How tight should plastic parts be?

Plastic parts need to be tightened by hand. They should be as tight as possible without risking damage.

Is it safe to use metal tools on plastic parts?

The use of metal tools is OK when great care is taken. It is more important that parts be screwed in place in the proper position; no amount of force can replace good alignment.

What tool should I use to tighten the worm gear clamps?

Some ring clamps come with thumb screws that allow tightening without tools. Others only require a screw driver. These should be tight, but should not be forced. It is possible that plastic parts could be broken with too much force.

Does it matter where I put the chiller?

Yes, the location of the chiller (above or below the tank) may alter the water pressure and flow rate in the system. While the pump can handle just about any arrangement, placing the chiller on the floor below an elevated tank will slightly reduce water flow and pressure. It is more important that tubes be free of kinks or excessive bends, so adding length to relax tubing is fine. The best place to put the chiller is directly below or to one side of the tank. It is best to put the chiller as close to level with the tank, but it is not required.

My tap water is discolored, is this ok?

All water will have some color, most often a faint green or white color. Tap water that is not acceptable might appear very cloudy or may have a strong chemical smell. If this is the case, an alternate source of water should be considered.

How do I know if my water is safe for trout?

Most tap water will be acceptable for use in this tank system. After a break in period of at least one week, there will be plenty of time for chlorine to dissipate, and for particulate matter to be filtered out. Unless your water appears to be totally unacceptable, it is probably safe for trout. The break-in period is an important part of this, so being safe after a week does not mean that water directly from the tap would be safe for fish.

What tools are needed for tank installation?

The only tools needed for tank installation are a screwdriver, knife or pair of scissors, and pliers to tighten any connections if needed. You may also need a clean 5 gallon bucket to assist in filling the tank and water changes. This can be purchased at any hardware store. Please rinse the bucket first and then do not use this bucket for anything other than tank water.

Do I need to age tank water before first filling the system?

No, the break in period will age the water before fish are introduced.

The tubing is very hard to fit over the plastic tank parts, what should I do?

If tubing doesn't fit over parts, it might help to dip the end of the tube in very hot water. This will momentarily soften the plastic allowing you to slide the tubing over the part.

Also, tubing can be carefully stretched by heating the ends, and then inserting a rigid object like a pair of scissors into the end. This applies pressure to the end and stretches it a small amount. Excessive force can break the tube end.

Tight tubing generally will fit, but it might require some time and patience.

Should I get a lid for my tank?

Yes, it is better to cover the tank with some material which can prevent objects from falling in, and provide the reduced light levels that fish prefer. Foam, screen, and plastic have all been used as lid materials with success. Purchased lids for the tank can also work, but because many of these include lights, it is important that the light feature not be used until the trout are out of the egg basket. Also, as the trout grow, they will start jumping for their food and could jump out of the tank!

Does my tank need insulation?

Yes, insulation will provide a darker, more stable environment for the fish. Insulation will reduce the amount of work needed to maintain the water temperature, saving electricity and limiting the amount of time the chiller will be operational. In addition, insulation will reduce condensation in a warm classroom.

What kind of insulation can I use?

There are many materials which can help insulate the tank. The most popular is foam sheet material, available at any home repair - industrial hardware store. Many other materials can work including plastic, wood, or cardboard.

Where do I position the air stone?

The air stone aeration system produces a large volume of bubbles. These bubbles can interfere with the filter operation by filling the motor with air and causing it to “air lock” and fail. For this reason, there should be at least 4 inches between the air stone and the filter.

I Ran out of Food. What do I do? You can use tropical fish food flakes or pellets. Make sure the pellets will fit in the trout’s mouths. Or you can contact your local TIC coordinator or Rob Tucker (see TIC Resources Section Page 42) and food will be sent to you.

Section XIII. Teaching Aids

Here are some teaching aids that will help you energize your students about TIC. While they are fun, they also help teach about trout.

Trout Coloring Features:

- The lateral line is often marked by color.
- Most trout have small spots.
- Many trout never lose their parr marks--- the dark, oval- shaped splotches along their bodies that can be a form of camouflage.
- Coloring of a trout often matches their environment to some degree.
- Males and females within a species can have different colors.
- Colors can change over the lifetime of a trout, usually becoming more distinct and vivid as they age.
- Trout colors become even more vivid at spawning time.

Color A Trout

Where are all
the trout?
Can you find
all 10?

ONCE I WAS A BABY TROUT

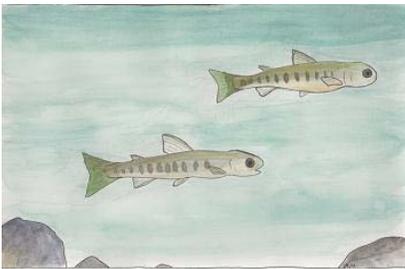

1. First I was a GREEN EGG sitting in my redd.
2. Then I was an EYED EGG, my eyes were on my head.

3. Then I started HATCHING; the egg shell left my back.
4. Then I was an ALEVIN with a big yolk sac.

5. Then I had to USE YOLK; I watched my belly shrink.
6. Then I was a LITTLE FRY—I wanted food, I think.

7. So I looked for BUGS TO EAT and I swam around.
8. Soon I had my PARR MARKS, so I couldn't be found.

The following images can be printed to show your students what their trout will look like when fully grown

Brook Trout

Section XIV. Potential National Funding Sources

TOSHIBA AMERICA FOUNDATION GRANTS

Applications for grants under \$5,000 are accepted year-round. Check the Web site for grades K-6 and 7-12 application rules. Deadline for grants over \$5,000: February 1st or August 1st The Toshiba America Foundation encourages teacher-led, K-12 classroom-based programs, projects, and activities that have the potential to improve classroom experiences in science, mathematics, and technology.

CAPTAIN PLANET FOUNDATION

The mission of the Captain Planet Foundation (CPF) is to support hands-on environmental projects for youth in grades K-12. Our objective is to encourage innovative activities that empower children around the world to work individually and collectively as environmental stewards. Through ongoing education, we believe that children can play a vital role in preserving our precious natural resources for future generations.

BEST BUY SUPPORT FOR INTERACTIVE TECHNOLOGY

The Best Buy (<http://www.BestBuy.com/>) te@ch program recognizes creative uses of interactive technology in K-12 classrooms. The purpose of te@ch is to reward schools for successful interactive programs they have launched using available technology. This program has deadlines; check the website to find them. To apply, educators must first register as an applicant and identify a Best Buy store within a fifty-mile radius of the school.

TOYOTA TAPESTRY GRANTS FOR TEACHERS

Open to K-12 teachers of science residing in the United States or U.S. territories or possessions. All middle and high school science teachers and elementary teachers who teach some science in the classroom are eligible. This program has deadlines; check the website to find them. Proposals must describe a project including its potential impact on students, and a budget up to \$10,000 (up to \$2,500 for mini-grants). Environmental Education is one of their three target categories.

DONORS CHOOSE

If you are a public school teacher, DonorsChoose invites you to submit a project proposal for materials or experiences that would help your students learn. Please note that teachers do not receive any monies. If a donor funds your proposal, DonorsChoose will purchase and deliver what you requested. We currently serve all public schools in Alabama, Chicago, Indiana, Los Angeles, Louisiana, Mississippi, New York City, North Carolina, the San Francisco Bay Area (Alameda, Contra Costa, Marin, Napa, San Francisco, San Mateo, Santa Clara, Solano and Sonoma counties), South Carolina, and Texas.

KIDS IN NEED TEACHER GRANTS

Kids In Need Teacher Grants provide K-12 educators with funding to provide innovative learning opportunities for their students. The SHOPA Kids In Need Foundation helps to engage students in the learning process by supporting our most creative and important educational resource - our nation's teachers. Businesses work through KINF to sponsor classrooms.

OUTDOOR CLASSROOM GRANT PROGRAM

Lowe's Charitable and Educational Foundation, International Paper and *National Geographic Explorer!* Magazine have teamed up to create an outdoor classroom grant program (TIC can be framed with stream study and release trips). The program focus is to engage students in hands-on natural science experiences and allow enrichment across the core curriculum. All K-12 public schools in the US are welcome to apply.

TARGET FIELD TRIP GRANTS

Education professionals who are employed by an accredited K-12 public, private or charter school in the United States that maintain a 501(c)(3) or a 509(a)(1) tax exempt status can apply for up to \$1,000 for a class field trip. Educators, teachers, principals, paraprofessionals or classified staff of these institutions must be willing and able to plan and execute a field trip that will provide a demonstrable learning experience for students.

Section XVI.

Letter of Understanding

Letter of Understanding

Date: _____

This letter of Understanding is between the _____ Chapter of the Virginia Council of Trout Council and _____(Teacher) of the _____ school district.

In exchange for participating in the Trout In The Classroom program (Program), the above chapter will provide, at no cost, all the necessary items needed (see Tank Set Up section) to establish and maintain the Program in the above named teacher’s classroom. In exchange, the Teacher acknowledges that the provided equipment is to be used exclusively for Program. If the above named teacher elects not to continue participating in the Program, all the equipment, less the supplies needed to test the water chemistry, will be returned to the _____ chapter.

The _____ Chapter has the discretion to allow the equipment to be used to raise other fish until 30 days before the Program will commence.

Agreed to by:

Teacher

Chapter
Virginia Council of Trout Unlimited

Section XVII. Sample Grant

Dear Staunton Augusta County Chapter of the Isaac Walton League

My name is XXXXXXXX and I am a XXXXXXXXXX at XXXXXXXXXXXX School in XXXXXXXX County. One of my goals as a 7th grade Life Science teacher is to capture student interest in the outdoors; which I believe many students have lost. In order to achieve this goal I am trying to implement the Trout in the Classroom Program from Trout Unlimited. This program will entail having a 55 gallon freshwater tank set up in the classroom. It will be equipped with the proper gear to incubate brook, rainbow, or brown trout eggs and raise the fry to maturity. In the spring, with the cooperation of the Department of Game and Inland Fisheries, students will release the trout in a nearby stream, as well as, perform on site water quality and macroinvertebrate tests.

I envision using Trout in the Classroom to touch on subjects cross the curriculum. In science, students will learn about habitats, ecosystems, and watersheds. This also provides students a Meaningful Watershed Educational Experience (MWEE) as intended by the Chesapeake Bay Educational Program and the Virginia Standards of Learning. Students will use math concepts such as graphing, measurement, and computation. Students will incorporate Language Arts, by learning new vocabulary, writing about their observations in their science journals, and create essays centered on conservation issues. In order to connect to Social Studies, students will learn about the different topography of Virginia and the popular land uses throughout the Commonwealth. Through this study, students can address the shrinking native trout waters throughout the state and the land uses that contribute to this habitat degradation.

Unfortunately, Trout Unlimited does not provide funding for this program, and teachers are left to seek out funding on their own. The total cost of the project is around \$1,000 dollars. The most vital part of the Trout in the Classroom system is the chiller, which costs around \$500 dollars. Without the chiller, the trout cannot survive. I am asking if your chapter would be willing to donate the funds necessary to purchase this chiller. However, any funding that you can provide will be helpful. Thank you for considering this request in order for students to make a connection with their community, recreational facilities, rivers/streams, and to learn how their actions in the Shenandoah Valley can impact their future.

This sample grant proposal was graciously provided by Courtney Rodgers, a Middle School Teacher at Wilson Middle School in Augusta County, who has participated in the TIC program for two years. She was successful in obtaining her grant.

Section XVIII

Sample Water Chemistry Log

Use this form, or one similar of your own design, to record the daily water chemistry readings. Additionally, record the amount of water removed (nearest gallon is fine) during each cleaning.

For accurate records at year-end, record the number of eggs and dead fish you remove. Doing it as it occurs will enable you to more accurately report your year end results.

School Name and Grade

Test Date	Water Chemistry Readings are in ppm or ppt					# Dead Fry	Water In/Out	Tank Cleaning	Live Alevin / Fry	Special Notes
	pH	Ammonia (NH3)	Nitrite (NO2)	Nitrate (NO4)	Temp (°F)					
10/06/08	7.4	0 ppm	4.0 ppm	0 ppm	50.8	2			259	
10/07/08	7.4									
10/08/08	7.4	0 ppm	took 3 different readings	0 ppm	51.3	1	2 exchanges	2/3 tank cleaned	258	
10/09/08	7.4	0 ppm	2.0 ppm	0 ppm	51.5	1	7 gal. exchanged	Bacteria added @ 9 am	257	
10/10/08	7.4	0 ppm	4.0 ppm	0 ppm	52.3	2	10 gal. exchanged		255	
10/13/08	7.8	0 ppm	4.0 ppm	0 ppm	50.2	-	2 exchanges			
10/14/08	7.8	0 ppm	4.0 ppm	0 ppm	52.1	2			253	
10/15/08	7.4	0 ppm	8.0 ppm	0 ppm	52.3	2	26 gal. exchanged	tank cleaned	251	

Section XIX. Release Day Activities as submitted by teachers

The following are some activities that our TIC teachers conducted on release day. The list is meant to share with you some ideas of what has done, not necessarily what you should do. Work with your local TU chapter and VGIF representative to find ways to put together a release day program.

- Water quality testing
- Macroinvertebrate collection and study
- Wetland habitat and stream studies
- School officials dressed up as trout (I have the pictures!)
- Fly fishing demonstration
- Fly tying demonstration
- Stream shocking by VGIF
- Tree identification
- Family day activities with scavenger hunt for nature items
- Student reunion at release day for previous students who participated in the TIC program
- Partnered with local high school Ecology clubs to talk about watershed and stream health and to assist with release day

Section XX. Thoughts on Classroom Activities

The following is a list of activities that our TIC teachers used during the school year to help students understand water quality and conservation. As with the release day activities, these are just food for thought. I am sure most of you are doing some or all of them now.

- Watershed studies using the CSI database
 - Comparing your release stream to others in the area
- Macroinvertebrate studies and identification
 - Discussing what the trout will eat when released
- Mapping of nutrient cycles
- Daily trout journals on tank activity
- Plotting nitrate and nitrite levels using different graph types
 - Cross education with Math Studies
- Trout dissection and anatomy
- Painting a background mural for the tank
- Trout life cycle
 - One class did a 9' Brook trout with the life cycle along the lateral line
- Participation in the Trout Tapestry
 - This year we want to do both a Virginia and a South Eastern Region tapestry with Tennessee, North Carolina, and Georgia
- Study of yolk development
- Oxygen absorption
- Acid Rain impacts
- Trout art
 - Conventional
 - Crayon, watercolor, markers, etc.
 - Non conventional
 - M & Ms
 - Spaghetti
 - Painted Plaster of Paris forms

The following are some things you might want to consider trying in your classroom:

- Hydroponic gardening – how plants can take the nutrients from your tank water to grow. This can be done either with plants having their roots suspended in the water or by raising a garden using regular water and waste water to compare the differences.
- Using tank waste water to develop a waste treatment facility

Don't forget to checkout www.troutintheclassroom.org for more classroom and program ideas.

And for those of you (and your students) who want to push the envelope, there is always YOU TUBE!!!!
